Structure of substances inducing polyphagy in plants. A. SICINSKI and A. GUSZTA (Compt. rend. Acad. Sci. U.R.S.S., 1935, 26, 441-446). The polyphagous action on plants of some carbocyclic and heterocyclic compounds is described. The regularities observed in the change of activity of carcinogenic compounds when certain groups are introduced also occur in the case of naphthalene and acenaphthalene derivatives with respect to their action on plants. The only exception is 1-nitronaphthalene, which is very active towards plants. Quinoline and 3 : 5-dibromopyridine are also active. The position of the substituent group is important and this is particularly noticeable with 1- and 2-substituted naphthalenes, many of the former being very active whilst the latter are all inactive. Plants are not all equally responsive to the active substances, the most susceptible being cereals, whilst leguminous plants are most resistant. Certain substances such as ethyl α -naphthoate, 3 : 5-dibromopyridine, and 1-nitronaphthalene are equally active towards all the plants tested (wheat, barley, pea, vetch, clover, flax, tobacco, and V. sativa).

GENERAL INFORMATION SHEET																																																																																																																																																																																															
1ST AND 2ND PROCESS						3RD AND 4TH PROCESS																																																																																																																																																																																									
PROCESSES AND PROPERTIES INDEX																																																																																																																																																																																															
<p><i>SC</i></p> <p>Haloid Derivatives of Aromatic Hydrocarbons and their bacteriolytic activity. A. SCHMIDK and A. GOLDBERG (Bulg. Acad. Sci. U.R.S.S., 1963, 28, 674-677; cf. A., 1963, III, 272).—The activity of the halogenoaromatics increases in the order Cl-, Br-, and I-. Introduction of a second halogen strongly reduces activity, and the effect depends on the position of the chlorine atom, for 1 : 4-dibromo is only slightly active, while 1 : 2-dibromoanthracene is inactive. Although naphthalene and its chloro and bromo derivatives are very active, 2-bromonaphthalene is quite inactive. The position of the halogen in the naphthalene mol. is very important, for 1- and 2-bromo-compounds are inactive, and only the 3-naphthyl-geno-compounds are active. Introduction of Br into <i>c</i>- and <i>β</i>-naphthoic acids, 1, 8-naphthalic acid, and <i>c</i>- and <i>β</i>-naphthyl-amines does not produce activity. 9 : 10-Dibromo-anthracene, 2-bromophenanthrene, 4-bromo- and 4 : 4'-dibromo-diphenyl are also inactive.</p>

Synthesis of 1-naphthalenoacetic acid. A. Shnuk and A. Guseva, *J. Applied Chem. (U.S.S.R.)* 14, 1031-5 (1941) (French summary); cf. *C.A.* 37, 20089. — Naphthalene (100 g.), 76 cc. 40% formalin, 110 cc. concd. HCl, and 82 cc. concd. H_2SO_4 are stirred at 26-30° for 20-3 hrs. It is advantageous to add the chloromethylating melt, gradually over the first 10 hrs. of reaction to avoid troublesome emulsions. The oily 1-(chloromethyl)naphthalene is sept., washed with Na_2CO_3 soln. and water; yield of crude is 120 g., contg. 70-80% chloromethylated product. The above (80 g.) is dissolved in 250 cc. $EtOH$, filtered, and the clear soln. is treated with 27 g. KCN in 150 cc. water and 46 cc. $EtOH$ and refluxed for 3 hrs.; after cooling, the mixt. is treated with 3 vols. of water and the *water* extd. with an org. solvent. The crude nitrile is boiled with 120 g. KOH in 320 cc. water for 8 hrs., cooled, extd. with an org. solvent, and the aq. soln. acidified with 60% H_2SO_4 with cooling to yield 40 g. crude $Cu(H_2O)_4Cl_2$, m. 116°; crystals from hot water gave a product, which is essentially pure 1-naphthalenoacetic acid, m. 120°. The chloromethylation yields appreciable amts. of 1,6-bis(chloromethyl)naphthalene, m. 124° (from $EtOH$), which with Zn and alc. HCl gave $Cu(H_2O)_4Cl_2$, the picrate of which was identical with that of 1,5-Cu(H₂O)₄Cl₂, m. 135-6°. G. M. Kosolapoff

Activity of hydrocarbons depends on influence by hydrogenation. A large number of compounds, and Acad. Sci. U.R.S.S., 1951, No. 600, p. 111, have been found to be active after hydrogenation, and it has been shown that the active hydrocarbons have no polyphenolic character. The following are examples: 1-methoxy-1,1,2,2-tetrahydro-1,2-dihydroxybenzene and 1-methoxy-1,1,2,2-tetrahydro-1,2-dihydroxy-1,1,2,2-tetrahydro-1,2-dihydroxybenzene, which are active than are 1-bromo- and 1-methoxybenzenes. Active hydrocarbons lose their activity after hydrogenation, whilst derivatives of hydrogenated hydrocarbons which have the active functional groups in the aromatic part of the system retain some, if not a very considerable part, of their former activity.

AUTHORS: Guseva, A.A. and Marmorshteyn, L.M.

TITLE: Relation of the resistivity of sedimentary rocks to their porosity and permeability magnitudes

PERIODICAL: Referativnyy zhurnal, Geofizika, no. 10, 1962, 16,
abstract 10A101 (Inform. byul. In-ta geol. Arktiki,
no. 25, 1961, 54-62)

TEXT: The resistivity ρ_r was measured on sandstone specimens, whose porosity K_{po} and permeability K_{pc} varied from 5.06 to 35.8% and from 0.25 to 4753 millidarsis respectively, the specimens being saturated with NaCl solution having a concentration of 50 g/l. For the studied specimens it is noted that there is a statistical relation between the parameter ρ_r and the magnitudes of K_{po} and K_{pc} . A generalized comparison of the parameters ρ_r and K_{po} was prepared. It shows that the scatter of points increases as K_{po} decreases. This is connected with the fact that the influence of the pore channel structure on the magnitude of ρ_r increases as K_{po} dim-

First Upper Cretaceous petroleum in Caucasus. D. V. Neimayev and A. D. Guseva (Dept. Geol. and Geochem. Moscow Univ.), *Fiziko-Marksi. Zh.*, 12, No. 6, pp. 100-104 (1957). — A petrographic description is given of the Sulfak anticline (10-18 km. from the Caspian sea between the rivers Garut-za and Rashlychek). Shallow oil deposits of petroleum and natural gas of the Upper Cretaceous period have been found. The anticline is of brachial type, braced by a series of ridges stretching in the northerly and northwesterly directions. Crude oil from this deposit contains 8.2-9.2% asphaltene, 0.4-0.8%, and bark paraffin was about 10%; d_{4}^{20} is 0.860-0.873, and the dynamic viscosity 26 centipoise at 20°. Not more than 20% b. up to 200°, the gasoline-kerosine fraction represents 37-45%, and 90% b. up to 550°. The gas produced consists mainly of CH_4 , with higher homologs 6-8% by vol., and CO_2 3-6%. TITLE:

On Several Benzothiazole Derivatives (O nekotorykh proizvodnykh benzotiazola). VI. On a New Method of Synthesis of 2-Hydrazine Benzothiazole Mono- and Dicarboxylic Acids (VI. O novom metode sinteza 2-gidrazinbenzotiazol-mono- i dikarbovykh kislot)

PERIODICAL:

Zhurnal obshchey khimii, 1959, Vol 29, Nr 6, pp 2068-2073 (USSR)

ABSTRACT:

The methods of synthesis of heterocyclic hydrazines, recorded in references 1-11, are not convenient for the synthesis of several benzothiazole derivatives, especially of benzothiazole mono- and dicarboxylic acids. According to Th. Curtius and E. Schmidt it had to be assumed, that the 2-aminobenzothiazole, in which the nitrogen atom of the amino group shows an apparently amidine character, could react with hydrazine hydrate just in the same way. The authors studied therefore the effect of hydrazine hydrate upon 2-aminobenzothiazole and its derivatives. When 2-aminobenzothiazole is heated with hydrazine hydrate dissolved in water at 120°, a vigorous formation of ammonia takes place. After precipitation of the product by cooling, it easily formed with the silver nitrate dissolved

in ammonia a layer of silver and condensed together with acetic acid ester to 1-benzothiazolyl-(2')-3-methylpyrazolene (Ref 7). Based on these results and also on the results of the analysis it could be established, that a splitting off of the amino group takes place in this reaction and benzothiazole-2-hydrazine (I) is formed. At a weak acidification of the solution and after removal of compound (I), a yellow oil, easily soluble in hydrochloric acid and sodium hydroxide, was separated. In open air it is quickly transformed into a crystalline product (II) the structure of which was proved by miscibility test. Thus a partial disruption of the benzothiazole ring and formation of the o-aminothiophenole (Ref 14)(Scheme), is effected by this reaction.. By longer heating the yield of 2-hydrazine benzothiazole decreases, whereas the yield of sulfide (II) increases. The same reaction with substituted 2-aminobenzothiazole did not succeed. Under the above named conditions the 2-aminobenzothiazole carboxylic acids react quite differently. When heating 2-aminobenzothiazole-6-carboxylic acid with hydrazine hydrate dissolved in water at 120-130°, the formation of ammonia ceased after 6-9 hours. The

SOV/79-29-6-63/72

product precipitated in acidification showed a reaction characteristic of the hydrazine group (layer of silver) and led by conversion with steaoryl acetate to the corresponding pyrazole derivative (Ref 16). The mentioned properties and data of synthesized compounds correspond to the structure analysis of synthesized benzothiazole-6-carboxylic acid (III) (85 % yield). Analogously compounds (IV-VI) were obtained (Ref 17) from the 2-hydrazinebenzothiazole-5,6-, 5,7-, and 6,7-dicarboxylic acids with satisfactory yields. There are 1 table and 20 references, 7 of which are Soviet.

photographic and optical properties of these azomethine dyes have been investigated, along with some properties of dyes obtained from them by color development (absorption spectra and stability). The introduction of the acyl residue into the amino group of the AD deepens their color, particularly in alcohol solutions. The absorption of the AD in gelatine emulsion is characterized by a hypsochromic shift of the absorption maximum compared with the alcohol solutions, and by a simultaneous broadening of the entire absorption band. Many investigated AD from the 1-aryl-3-acylaminopyrazolone series are quite active under color development and form highly stable dyes. The latter pertains also to AD from the series of 3-N-alkyl (aryl)-N-acylaminopyrazolones, but unlike the preceding series these AD have a small reactivity. Bibliography, 21 titles. A. Title : Outer-molecular reactions and chromatism. Part 5.- Absorption spectra of molecular complexes nitro-compounds and aromatic amines

Periodical : Zhur. ob. khim. 24/8, 1402 - 1415, August 1954

Abstract : A method of analyzing nitro-aromatic amine combinations by studying the absorption spectra of their molecular complexes, is described. A hypothesis was made that the reaction between molecules in such complexes activated by exomolecular forces may result in the formation of a special type of partial electron bond with the participation of π -electrons. The reduction in excitation energy, as result of reaction of two polar-opposite chromophoric systems, is explained. Seventeen references: 10 USSR; 2 USA and 5 German (1910 - 1953). Tables; graphs.

16A

Dismutation of hydroaromatic ketones. A. N. Guseva. *Vestn. Mosk. Univ.*, 1947, 13(1-3).—Summary of a thesis. In analogy with Zelinskii's (*C.A.*, 19, 1201) conversion of methylenecyclohexane into PhMe and methylcyclohexane, cyclohexanone in the presence of Pt and Pd catalysts at 180–200°, in a slow stream of CO₂ give 80% of a mixt. of PhOH and cyclohexanol; part of the latter undergoes dehydration and the resulting cyclohexene undergoes conversion into a mixt. of cyclohexane and C₆H₆. Under the same conditions, 2-methylcyclohexanone is converted into 2-methylcyclohexanol and cresol; the secondary reaction results in 1-methylcyclohexene, methylcyclohexane, and PhMe. Menthone gives a mixt. of menthol, thymol, menthene, menthane, and *p*-cymene. The ams. (in mole %) of the reaction products (aromatic hydrocarbon, cyclohexane hydrocarbon, cyclohexene hydrocarbon, phenol, hydroaromatic alc.) are: from cyclohexanone, 12.12, 10.39, traces, 32.85, 39.1; from methylenecyclohexanone, 12.6, 20.06, traces, 32.22, 33.80; from menthone, 4.0, 6.9, traces, 45.30, 44.80. Cyclopentanone suffers no change over Pt at 200°; ketones with the CO group outside the ring undergo no dismutation. Ni catalysts, Al₂O₃, and Cr₂O₃ also promote the dismutation of cyclohexanone but only at a higher temp. and to a lesser extent. In contrast to Zelinskii's reaction with methylenecyclohexanes, dismutation of the cyclohexanones is reversible; from a mixt. of a hydroaromatic alc. and the corresponding phenol in the mol. ratio 2:1, 10–15% hydroaromatic ketones are obtained: cyclohexanol + PhOH give cyclo-

hexanone, methylcyclohexanol + *o*-cresol give methylcyclohexanone, menthol + thymol give menthone. Cyclohexanone oxime on platinized C at 20° in vacuo forms partly (besides decompn.) PhNH_2 , and cyclohexylamine. N. Thun.

TITLE: Characteristics of the Infra-Red Absorption Spectra
of Solid Petroleum Paraffins

PERIODICAL: Khimiya i tekhnologiya topliv i masel, 1961, No. 2,
pp. 59-62

TEXT: The infra-red absorption spectra of very narrow fractions of solid petroleum products exhibiting carbamide complexes have been studied in the region $700-750 \text{ cm}^{-1}$. Previous published data referred only to individual hydrocarbons, and it was claimed that n-paraffins could be distinguished from the others (iso- and cycloparaffins) by a strong shoulder at 732 cm^{-1} . This has now not only been disproved, but there is also no clear correlation at all between absorption spectrum and physico-chemical structure, although a dependence of spectral shape on melting temperature has been found. Petroleum crudes and fractions of the following origins were studied: Ozek-Suat, El'sk, Chalodidi, Sell, Shirvanskaya. They were fractionated from a benzol solution of the complex formed by them and methanol saturated with carbamide, and the complex was broken by heating with

Card 1/3 ✓

Characteristics of the Infra-Red Absorption Spectra of Solid Petroleum Paraffins

distilled water to 90°C. They were then split into about 50 fractions according to melting point between 19.5 and 68.2°C, and each is characterized by a sum factor, $\Phi_c = 2(10^3 n_D^{90} - 1400) / 0.84 t_{MP}$, which measures the deviation from the n-paraffin structure, where t_{MP} is the melting temperature. The spectra obtained are reproduced in the article. The spectra were obtained from thin films mounted on a sodium-chloride crystal spectrometer WKC-12 (IKS-12) at room temperature, with specimen and slit size adjusted for maximum resolution. It is seen that the 720 line is alone in the low melting specimens, but the 732 line increases in size with melting point until a 732/720 doublet is formed. The 720 line is usually ascribed to (CH₂) chain deformation, and the 732 to the crystal structure. The gradual change of spectral type with melting point is suggestive of the phase change which occurs around C₂₂, (which corresponds to a melting temperature of 44.0°C, and is hence in the region studied here), but any stronger suggested correlation would be sheerly speculative at present. There are

AUTHOR: Guseva, A. N.; Leyfman, I. Ye.; Ashkinadze, L. D.

TITLE: Investigation of solid petroleum paraffins by refraction and IR-absorption spectra

SOURCE: IVUZ. Neft' i gaz, no. 4, 1963, 49-53

TOPIC TAGS: hydrocarbon fraction, carbamid complexes, IR-absorption, solid petroleum paraffin

ABSTRACT: It was found in the investigation of petroleum paraffins that the changes in the structure of those paraffins which form carbamid complexes and which are dependent upon temperature are reflected in the intensity and form of infrared absorption in the region of 720 cm^{-1} . These changes are fixed on the refraction curves at the same temperature levels. The limits of existence of various phases and phase transitions are determined according to the temperature dependence, the form of the infrared absorption in the region of 720 cm^{-1} , and the changes of the crystal structure of petroleum paraffins. These interpretations of various infrared spectra of petroleum paraffin fractions were taken at room temperature. The methods used in this study can be applied to the

TITLE: Characterization of solid petroleum paraffins on the basis of the infrared absorption spectra in the region 700 cm^{-1}

PERIODICAL: Akademiya nauk SSSR. Izvestiya. Seriya fizicheskaya, v. 27, no. 1, 1963, 104 - 107

TEXT: A study is made of the spectra of more than 80 fractions of petroleum paraffins (part of them forming carbamide complexes) in order to characterize the solid petroleum paraffins having different chemical structures on the basis of their absorption characteristics between 700 and 750 cm^{-1} . The fractions of the complex-forming hydrocarbons were produced by fractionating paraffins with carbamide and from 50° -distillate fractions of mineral oils. The residua of the solid hydrocarbons not reacting with carbamide, were fractionated by chromatography on charcoal. The deviations of the properties of the fractions from those of the n-paraffins are characterized by the sum factor $\phi_c = 2 \cdot (10^3 n_D^{90} - 1400) - 0.84 t_{sol}$ where n_D^{90}

denotes the refractive index and t_{sol} is the solidification temperature. The fractions separated at $t_{sol} = 19.5$ to 68.2°C are mainly n-paraffins with possible admixtures of iso and cycloparaffins. The hydrocarbons forming no complexes differ more strongly from the n-paraffins. The paraffin fractions not forming complexes contain a large number of methyl groups. In the range from 700 to 750 cm^{-1} the character of the absorption bands depends on t_{sol} . Probably the changes in the spectra of the petroleum paraffins are connected with the formation of crystal structures. There are 2 figures.

SOURCE: Neftekhimiya, v. 5, no. 5, 1965, 786-790

TOPIC TAGS: hydrocarbon, alkane, fuel, solubility

ABSTRACT: A number of theoretical problems in petroleum geology depend for their solutions on information concerning the solubility of hydrocarbons in water under various conditions. This work expanded and refined the work of other investigators in this area. The following are the main conclusions reached. The solubility of alkanes in water decreases with increasing molecular weight. The solubility of branched isomers is lower than that of straight-chain alkanes. With rising temperature, the solubility of gaseous alkanes first decreases, and then increases. The inflection point of the solubility curve shifts toward lower temperatures with increasing molecular weight of the hydrocarbon. The solubility of liquid alkanes increases sharply with rising temperature in any temperature range. The solubility of water in alkanes increases with rising temperature and increasing molecular weight. The solubility of water in gaseous alkanes is independent of molecular weight and decreases with increasing pressure. Orig. art. has: 1 table and 3 figures. (VS)

Title : History of Creation and Condition of Plantations of the Dorkul' Stations for Shelterbelt Forest Cultivations

Orig Pub : Tr. In-ta losa AN SSSR, 1956, 30, 7-31

Abstract : The prosenco is noted of a great quantity of plantations of the IV-V quality classes and of plantations of poor and short-lived species, as well as mass drying of stands 45-50 years old, as a result of unsatisfactory management of the farm. For the cultivations of shelter plantations with oak predominating, a series of agroengineering methods and forest managament improvements is recommended.

TITLE: Wear resistance of W-Co hard-alloy cutter tips in machining EI437 alloy

PERIODICAL: Stanki i instrument, no. 6, 1961, 32-33

TEXT: Results are given of an experimental investigation with W-Co alloy-tipped cutters in turning cylindrical smooth and grooved blanks of $\text{EI}437$ heat-resistant alloy. The experiments were performed on a Gustlow Werke lathe, using a cutting speed $v=30 \text{ m/min}$, cutting depth $t=1.0 \text{ mm}$ and feed rates s of 0.6 and 0.3 mm/rev for continuous cutting (on smooth blanks); intermittent cutting (grooved blanks) was done with $v=10 \text{ m/min}$, $t=1.0 \text{ mm}$ and $s=0.2 \text{ mm/revolution}$, and with $v=6 \text{ m/min}$, $t = 1.0 \text{ mm}$, and $s=0.6 \text{ mm/rev}$. Wear on the rear face of the tips was used as a criterion of the wear. The results are illustrated in four graphs (Fig. 1-4). It was established that 8% Co gave the maximum wear resistance and hardness. A Co content lower than 8% gave lower wear resistance on account of insufficient alloy strength (the cutting edge crumbled), and higher than 8% also resulted in lower wear resis-

Wear resistance of W-Co ...

tance on account of insufficient hardness. A lower feed rate facilitated cutting and raised wear resistance. It was concluded that the cutter tips used for machining EI437 alloy must have higher strength than those used for cutting cast iron or steel. The maximum wear resistance for continuous cutting of EI437 is shown by cutter tips with 8% Co; for intermittent cutting of cast iron and steel the Co content in W-Co alloy cutting tips must be lower. There are 4 figures and 2 Soviet-bloc references.

TITLE:

Alloys on the TiB_2 basis for cutting tools

PERIODICAL:

Vestnik mashinostroyeniya, no. 8, 1962,
44 - 47

TEXT: The authors describe a series of experiments conducted in order to establish the physical, mechanical and cutting properties of TiB_2 alloys. Specimens of 15 alloys containing various percentages of TiB_2 and bounding metals (Fe, Co, Ni) were tested for bending, hardness, and coefficient of friction. Their cutting properties under various working conditions were also investigated and the results of the experiments recorded in form of tables and graphs, and analyzed. TiB_2 alloys (obtained by powder pressing and baking process) possess many advantages
